

1. No Aliasing Between Pointers ----- no two memory pointing same location
2. Correct Usage with Function Calls ----- using restrict
3. No Aliasing Between Loops or Different Array References ----
-no similar loop/array can not be used
4. Complex Data Types (e.g., Structs)

inline

1. Small and Simple Functions
2. Avoid Inlining Complex Functions ----- complex not use
3. Functions that Are Called Frequently ----- frequently called function
4. Inline Functions and Recursion ----- recursion not suitable
5. Use with Constant or Known Expressions ----- Simple, constant operation

give relation for block format with vector gor

The **block format** for audio data storage and `#pragma vector_for` can be related in the following way:

Block Format and `#pragma vector_for`

In block format, each channel's audio data is stored separately in blocks corresponding to a specific time frame. This layout allows each channel's data to be accessed independently, which aligns well with the requirements for vectorization.

1. **Independence of Loop Iterations:** In block format, data for different channels is separated, and there is no dependence, ↓ between the samples from different channels within a block. This makes it suitable for vectorized operations. For example, if we are
